

“Some of My Laborers Don’t Think They’ll Like It...”

By Justin Breithaupt, Jr.; Non-Stop Scaffolding, Inc.

This is something we’ve heard a lot in the past. Here’s how it goes: we approach a masonry contractor about the possibility of using Non-Stop and he says, “I’ve asked my guys what they think about it, and some of them don’t like it, “ or “my men don’t want to use anything but frames.”

Now, is it the bricklayers or the laborers saying that to the boss? In our experience, we’ve **never** met a bricklayer who didn’t **love** working on Non-Stop. Eliminate all the bending down and reaching up to lay 35-pound blocks and that bricklayer is going to hug you. And it’s the bricklayers that make your money - let’s keep them happy. Actually, all the resistance comes from the laborers. Let’s try to figure out why.

You build Non-Stop once, at the beginning of the job, on the ground, no climbing. Nothing weighs more than a sack of mix. It takes about half as much time as frames. From then on, the towers are moved from wall to wall with a forklift. That eliminates all the scaffold and building and tear-down for the *entire duration of the job!* **The laborers ought to like that.**

Non-Stop lets you start the wall right off the scaffold. The bricklayers walk on the ground and the laborers walk on the scaffold. When the wall gets to a comfortable height, the bricklayers’ walkboards are dropped in place in about 30 seconds. Nobody moves. There is no 20-minute break because they got scaffold-high. Everyone just keeps on working. That’s less work for the laborers. **They ought to like that, too.**

On frames, the laborers have to raise the boards and leftover material every 4 to 6 feet. That’s about a 20-minute pain-in-the-behind (and hazardous) job they do several times a day. There’s none of that on Non-Stop, they just keep tending. **They ought to really like that.**

So what’s left for the laborers to do? Tend the masons and raise the scaffold. The laborers raise the scaffold every 20 minutes or so. They crank for about 3 minutes and tend for about 20 to 30. Cranking is easy due to the winch gearing. You can land a pallet of split-faced 12s and crank it one-handed. They stay with their bricklayers all day long and keep them covered up with materials. **That’s all.**

We still don’t see a problem.

So why are the laborers against it before they even use it? **Fear of something new.** All they’ve ever known their whole lives is building and tearing down frames, hopping planks every 4 to 6 feet, and re-handling leftover materials. When they start working on Non-Stop, life’s a whole lot simpler, but it’s **different**, and it takes about a week to get used to something that’s new and different, even if it’s better for you. But they will gripe and complain at first. Ask contractors who routinely use Non-Stop and they’ll tell you their laborers prefer it over frames once they make friends with it, but it takes about a week.

A case in point: An old friend of ours, Red Vidrine in Ville Platte, LA, tells the story of a school addition job. It was multiple classroom wing additions, all identical. He took his new Non-Stop scaffolding out to the job and asked one of his foremen if he would give it a try. The foreman said he’d rather not, he could do just fine with his frames. Red asked another foreman and this one said sure let’s give it a try. As Red tells it, “That foreman finished an identical wing 3 weeks ahead of the first guy and they liked the scaffold just fine. I had three weeks worth of payroll money I got to keep for myself. Now I just go out to the job and say, ‘Here’s your scaffold. Use it.’”
